Section 1

Overview of project

A. Where we have uploaded our tutorial

<https://github.com/Bavani94/Greenhouse-IoT->

B. Why have we chosen to upload to this site

GitHub is a development platform build for developers. From open source to business. User can host and review the codes, manage projects or even build software alongside millions of other developers. **GitHub** is a web-based Git repository and Internet hosting service.

C. What have we uploaded

All the codes, Step by step tutorial, Guide on how to setup Twilio, Firebase and AWS, CA2 folder which consists of the .fzz files

D. What is the application about?

The aim of this project was to design and build a greenhouse that helps to sustain plant life automatically without human intervention, by acting upon live sensor readings and be able to display the status of the system to the owner.

The project was split into two parts: programming that manages the sensors and transducers; and creating a web application to allow the user to interact with the greenhouse.

E. Summary of the steps that will be described

Provide a bullet list of the steps that will be covered in the other parts of this tutorial

Section	Description
1) Overview	Get an overview of what you will do for the lab
Sections 2 to 5 will guide you through the steps of the building of greenhouse	
2) Hardware requirements	Provides overview of hardware required
3) Connect The Components	Guide you on how to connect the T-Cobble to Hardware
4) Softwares/External Libraries /Templates	Shows the Softwares/External Libraries /Templates that are being used
5) Programming Codes	Shows the code

Section 2

Hardware Requirements

Hardware Background

Background

This section talks about which environmental factors will be monitored by the automated system and discusses the choices of sensor or actuator that were available to use.

Temperature

The temperature of the environment is extremely important for plants as it affects multiple growing factors. Extreme temperatures can negatively impact plant productivity so maintaining the temperature in a greenhouse is crucial. Each plant also has its own specific temperature range so being able to adjust the settings in the greenhouse is equally as important.

Humidity

Humidity is the measure of how much moisture is present in the air. When plants transpire, water vapour is released from the leaves, increasing the humidity.

A high humidity can be fatal to plants if it is not monitored, as a build-up of moisture on plants. It is important to make sure that air is circulating through the greenhouse to reduce the water vapour around the plants.

Light

Plants use the energy from light for photosynthesis and so without light, plants would not be able to grow. Different plants need different amounts of light but if a plant receives too little light then problems will start occurring, such as

- Leaves turn yellow
- Leaves are too small
- Leaves dry up

Soil Moisture

Water is another key element in photosynthesis. Plants absorb water through their roots where it then travels up the stem and into the leaves where photosynthesis occurs. It's important to monitor the moisture levels in the soil, making sure that there is enough water for the plant but also taking care not to over saturate the soil, as this could cause the roots to rot.

Water Pump

Remembering to water the plant can be hard when we are busy. So instead of being countless disappointing harvests, a water pump can be used to maintain the water levels in the soil.

Small Fan

It will help to move air around to simulate humidity control so that there will be air for the plant

Hardware Design

Design

The temperature, humidity, light and soil moisture levels as these are four of the most important environmental factors during plant growth. The design step for this was to think about what can be done to control these factors.

Dealing with Temperature

All plants have a temperature range that they grow best in, which is why we see different plants at different times of the year. Greenhouse should be able to maintain a specific temperature range for however long is necessary.

If the temperature exceeds the maximum allowed temperature, the greenhouse needs cooling down in some way. In industry this would usually be achieved by opening vents or turning on fans, letting air circulate through the greenhouse. When the temperature becomes too low, the greenhouse would need to be heated up and all vents and fans would be closed and powered down.

For the project, fans is being used to turned on when the temperature is too high. If the temperature becomes too low.

Dealing with Humidity

The most effective way to maintain a low humidity is to keep the greenhouse dry, which can be done by warming up plants and keeping air circulating through it. If the humidity is too low however, then moisture needs to be added to the air.

The fans mentioned in 'Dealing with Temperature' can be used to reduce the humidity if it becomes too high.

Dealing with Soil Moisture

Plants absorb water through their roots for use in photosynthesis. This, along with other factors, such as a high temperature, will dry out the soil. Maintaining the soil moisture content is therefore essential for plants to continue to grow healthily and can be achieved in different ways. One of which would be to sprinkle water on the soil after a certain period.

Hardware Checklist

Temperature and Humidity

The DHT11 is a basic, digital temperature and humidity sensor. It will be used to track the temperature and humidity of the immediate surroundings of the plant. It's simple to use but requires careful timing to capture data.

The sensor has 4 pins

- VCC (this is where you connect to power)
- DATA (this is an output value you read to determine)
- NC (stands for no connection)
- GND (connect to ground)

Light Resistant Diode (LDR)

It's a light sensitive resistors which change resistance based on how much light they are exposed. It helps to track the light levels in the enclosure. This is not particularly good for accurate measurements but it is enough to indicate when it becomes dark.

LED

The longer leg (anode) should be connected to the positive supply of the circuit (power). The shorter leg (cathode) should be connected to the negative side of the power supply (ground). It will only work if the power is supplied in the correct way. LED will light up the enclosure when light levels are Low.

Soil Moisture Sensor

The Soil Moisture sensor can read the amount of moisture present in the soil surrounding it. It's a low tech sensor, but ideal for monitoring gardens. It is used for the soil moisture measurements as it will be inserted into the soil to track the soil moisture.

Small Generic FAN

The Fan voltage is about 6 and it is to move air around to simulate humidity control so that the air can flow all the way through it. Whether the fan is used to take in or extract air simply depends on which direction it is facing, there is no difference in the way it is controlled.

Section 3

Connect your Components

Section 4

Softwares/External Libraries/Templates

Operating System:

Database:

- Firebase (<https://firebase.google.com/>)
- AWS (<https://aws.amazon.com/>)

SMS Service:

- Twilio (<https://www.twilio.com/>)

- To view step by step guide to create the Database and SMS Service go to another PDF file if not to the github link which is even in the first part .

External Libraries:

- Pyrebase (Firebase Library) (<https://github.com/thisbejim/Pyrebase>)
- PyCloudinary (Cloudinary library, where our images will be stored) (<https://github.com/cloudinary/pycloudinary>)
- gpiozero (<https://gpiozero.readthedocs.io/en/stable/>)

Templates:

-

Section 5

Programming Codes

A. Write code for dht22_test.py

- Create a python script dht22_test.py
- Sudo nano ~/CA2/ /dht22_test.py

```
import sys
import Adafruit_DHT
from time import sleep

pin = 26

while True:
    humidity, temperature = Adafruit_DHT.read_retry(11, pin)
    print('Temp: {:.1f} C'.format(temperature))
    print('Humidity: {:.1f}'.format(humidity))
    sleep(1)
```

B. Write code for fan_test.py

- Create a python script fan_test.py
- Sudo nano ~/CA2/ /fan_test.py

```
#!/usr/bin/python
import RPi.GPIO as GPIO
import time

GPIO.setmode(GPIO.BCM)

# init list with pin numbers
pinList = [12]

# loop through pins and set mode and state to 'high'
for i in pinList:
    GPIO.setup(i, GPIO.OUT)
    GPIO.output(i, GPIO.HIGH)

# time to sleep between operations in the main loop
SleepTimeL = 2

# main loop
try:
    GPIO.output(12, GPIO.LOW)
    print "ONE"
    print ("Fan is on.")
    time.sleep(60);
    GPIO.cleanup()
    print "Good bye!"

# End program cleanly with keyboard
except KeyboardInterrupt:
    print " Quit"

# Reset GPIO settings
GPIO.cleanup()

# find more information on this script at
# http://youtu.be/WpM1aq4B8-A
```

C. Write code for full.py

- Create a python script full.py
- Sudo nano ~/CA2/ /full.py

```
#!/usr/bin/python
import RPi.GPIO as GPIO
import time

GPIO.setmode(GPIO.BCM)

# init list with pin numbers

pinList = [4, 17, 27, 22]

# loop through pins and set mode and state to 'high'

for i in pinList:
    GPIO.setup(i, GPIO.OUT)
    GPIO.output(i, GPIO.HIGH)

# time to sleep between operations in the main loop

SleepTimeL = 60
GPIO.setup(20, GPIO.OUT)
GPIO.setup(21, GPIO.OUT)
# main loop

try:
    GPIO.output(17, GPIO.LOW)
    GPIO.output(4, GPIO.LOW)
    print "Fan and Lights are ON"
    GPIO.output(20, GPIO.HIGH)
    print "Buzzer is ON"
    GPIO.output(21, GPIO.HIGH)
    print "Light is ON"
    time.sleep(SleepTimeL)
    GPIO.cleanup()
    print "Good bye!"

# End program cleanly with keyboard
except KeyboardInterrupt:
    print " Quit"

# Reset GPIO settings
GPIO.cleanup()

# find more information on this script at
# http://youtu.be/WpM1aq4B8-A
```

D. Write code for firebase_data.py

- Create a python script firebase_data.py
- Sudo nano ~/CA2/ /firebase_data.py

```
import pyrebase
import time
from AWSIoTPythonSDK.MQTTLib import AWSIoTMQTTClient
import json

# Configure Firebase
